# Data Exploration and Data Visualization

18

by <b>Patrick Boily</b> ,	with c	ontribut	ions	from	Ehssan	Ghashim	and	Maia
Pelletier								

Why do we display evidence in a report, in a newspaper article, or online? What is the fundamental goal of our charts and graphs? Representating data properly, in a manner that allows an audience to gain insight about the underlying situation, is, without a doubt, one of the most important skill a data scientist and/or quantitative consultant must possess.

In this chapter, we introduce some commonly-used charts, discuss the fundamental principles of analytical designs, and give a brief overview of dashboards. A **substantially** more thorough treatment (including storytelling with data, the grammar of graphics and its implementation in R and ggplot2, and the basics of Power BI) is available in [1].\*

Interested readers should also consider consulting the following indispensable data visualization resources: [2, 3, 7, 13, 16, 18, 19, 20, 21, 22], among others.

### 18.1 Data and Charts

As data scientist Damian Mingle once put it, modern data analysis is a different beast:

"Discovery is no longer limited by the collection and processing of data, but rather management, analysis, and visualization. [15]"

What can be done with the data, once it has been collected/processed?

Two suggestions come to mind:

- analysis is the process by which we extract actionable insights from the data (this process is discussed in later subsections), while
- **visualization** is the process of presenting data and analysis outputs in a visual format; visualization of data *prior* to analysis can help simplify the analytical process; **post-**analysis, it allows for the results to be communicated to various stakeholders.

In this section, we focus on important visualization concepts and methods; we shall provide examples of data displays to illustrate the various possibilities that might be produced by the data presentation component of a data analysis system.

<sup>\*</sup> In this chapter, we preview (roughly) Sections 1.3, 1.5, and 2.3 of [1].

### 18.1.1 Pre-Analysis Uses

Even before the analytical stage is reached, data visualization can be used to set the stage for analysis by:

- detecting invalid entries and outliers;
- shaping the data transformations (binning, standardization, dimension reduction, etc.);
- getting a sense for the data (data analysis as an art form, exploratory analysis), and
- identifying **hidden data structures** (clustering, associations, patterns which may inform the next stage of analysis, etc.).

### **18.1.2** Presenting Results

The crucial element of data presentations is that they need to help **convey the insight** (or the message); they should be clear, engaging, and (more importantly) readable. Our ability to think of questions (and to answer them) is in some sense **limited by what we can visualize**.

There is always a risk that if certain types of visualization techniques dominate in evidence presentations, the kinds of questions that are particularly well-suited to providing data for these techniques will come to dominate the landscape, which will then affect data collection techniques, data availability, future interest, and so forth.

**Generating Ideas and Insights** In *Beautiful Evidence* [18], E. Tufte explains that evidence is presented to assist our thinking processes. He further suggests that there is a symmetry to visual displays of evidence – that visualization consumers should be seeking exactly (and explicitly) what the visualization producers should be providing, namely:

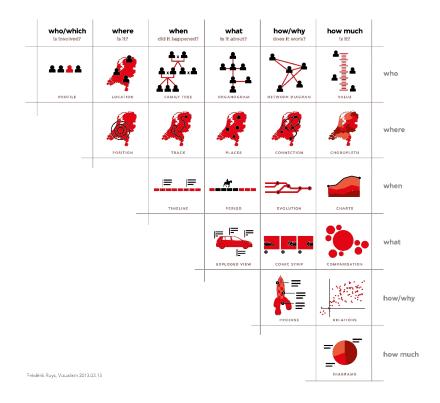

- meaningful comparisons;
- causal networks and underlying structure;
- multivariate links;
- integrated and relevant data, and
- a primary focus on content.

We will discuss this further in Section 18.2.

**Selecting a Chart Type** The choice of visualization methods are strongly dependent on the analysis objective, that is, on the **questions that need to be answered**. Presentation methods should not be selected randomly (or simply from a list of easily-produced templates) [1].

In Figure 18.1, F. Ruys suggests various types of visual displays that can be used, depending on the objective:

- who is involved?
- where is the situation taking place?
- when is it happening?
- what is it about?
- how/why does it work?
- how much?

**Figure 18.1:** Data visualization suggestions, by type of question [F.Ruys, Vizualism.nl].

A general dashboard should at least be able to produce the following types of display:

- charts comparison and relation (scatterplots, bubble charts, parallel coordinate charts, decision trees, cluster plots, trend plots);
- choropleth maps (heat maps, classification maps);
- network diagrams and connection maps (association rule networks, phrase nets),
- univariate diagrams (word clouds, box plots, histograms).

### 18.1.3 Multivariate Elements in Charts

It is not unusual to see modern datasets with 5, 10, 100, or even 1000+ variables. **High-dimensionality** brings a host of problems;<sup>1</sup> from a data visualization perspective, the challenge is that at most two attributes can be represented by position in the plane. How can we then represent other crucial elements on a flat computer screen or a piece of paper?

Potential solutions include using a **3-dimensional physical display** (such as one produced by 3D printing), or, more reasonably, one of the following **visual elements**:

- marker size,
- marker colour,
- colour intensity and value,
- marker texture,

- line orientation,
- marker shape, and/or
- motion/movie.

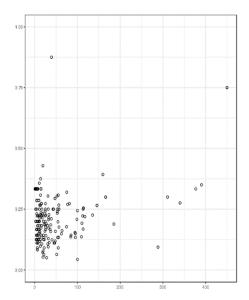

These elements do not always mix well – there can be "too much of a good thing", so to speak.

1: Such as the **curse of dimensionality**, which is remedied by feature selection and dimension reduction (see Chapter 23).

2: Efficient design is as much art as it is science: while we do want to highlight multivariate relationships, we do need to keep things "parsable". Less is more, as long as "less" is enough.

In practice, human brains can reasonably be hoped to integrate 4 or 5 design elements in a chart (including 2 reserved for position), together with a motion component; the use of additional design elements tends to complicate matters and confuse the reader more than anything.<sup>2</sup>

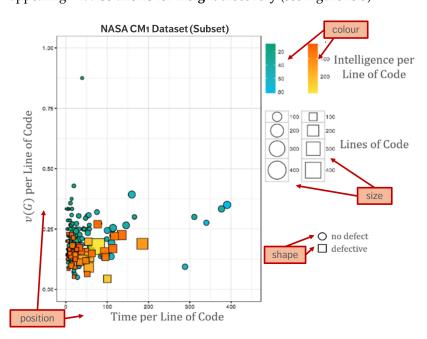

In Figure 18.2, we provide a two-dimensional scatterplot display of a subset of the NASA CM1 dataset  $\[ \]$  .

**Figure 18.2:** Scatterplot of a subset of the NASA CM1 dataset (minimalist).

3: Who could blame anyone for skipping over this chart entirely on their way to more entertaining fare? Is there **anything** of even remote interest that can be said about the chart and the underlying data?

We went out of our way to find a display that is as **uninformative** as it is dull – you will agree that we succeeded in our attempt.<sup>3</sup> The addition of data-aligned design elements does not only make the chart more appealing – it also allows for **insight discovery** (see Figure 18.3).

**Figure 18.3:** Bubble chart of a subset of the NASA CM1 dataset (with 5 variables).

4: True, this might not come as much of a surprise, but even such simple insights as these remain unreachable from Figure 18.2 alone.

For instance, we can see that defective components tend to contain more lines of code than non-defective components, *on average*, and that components for which more time was spent per line of code tend to be non-defective.<sup>4</sup>

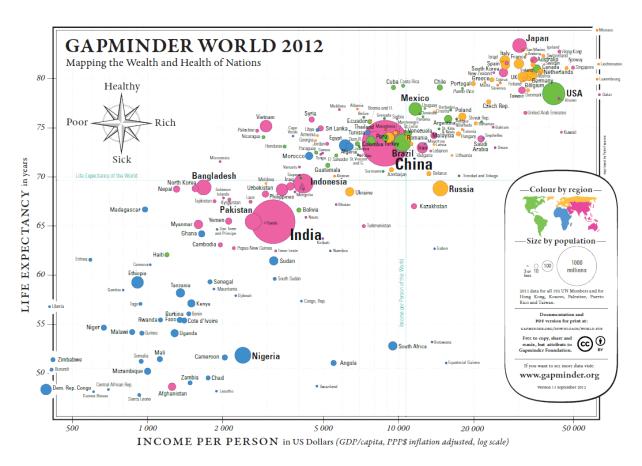

Figure 18.4: Gapminder's Health and Wealth of Nation (2012) [17].

**Example: Bubble Chart** Health and Wealth of Nations (Figure 18.4).

### Data:

- 2012 life expectancy in years
- 2012 inflation adjusted GDP/capita in USD
- 2012 population for 193 UN members and 5 other countries

### Some Questions and Comparisons:

- Can we predict life expectancy given a GDP/capita?<sup>5</sup>
- Are there outlier countries?<sup>6</sup>
- Are countries with a smaller population healthier?<sup>7</sup>
- Is continental membership an indicator of health and wealth levels?<sup>8</sup>
- How do countries compare against world values for life expectancy and GDP per capita?<sup>9</sup>
- Multivariate Elements: position for health and wealth, bubble size for population, colour for continental membership, and labels to identify the nations.

### Comments:

- Are life expectancy and GDP/capita appropriate proxies for health and wealth?
- A fifth element could also be added to a screen display: the passage of time. In this case, how do we deal with countries coming into existence (and ceasing to exist as political entities)?

- 5: The trend is linear: Expectancy  $\approx 6.8 \times \ln \text{GDP/capita} + 10.6$
- 6: Botswana, South Africa, and Vietnam, among others, at a glance.
- 7: Bubble size seems uncorrelated with the axes' variates.
- 8: There seems to be a clear divide between Western Nations (and Japan), most of Asia, and Africa.
- 9: The vast majority of countries fall in three of the quadrants. There are very few wealthy countries with low life expectancy. China sits near the world values, which is expected for life expectancy, but more surprising when it comes to GDP/capita compare with India.

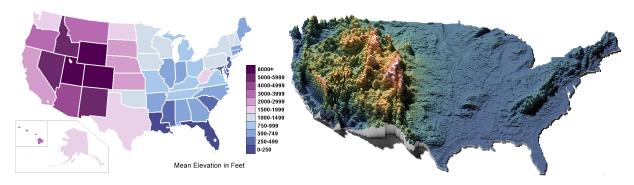

Figure 18.5: Mean elevation by U.S. state, in feet (left, source unknown); high resolution elevation map (right, by twitter user @cstats).

**Example: Choropleth Map** Mean Elevation by U.S. State (Figure 18.5).

- **Data:** 50 observations, ranging from sea level (0-250) to (6000+)
- Some Questions and Comparisons:
  - Can the mean elevation of the U.S. states tell us something about the global topography of the U.S.? <sup>10</sup>
  - Are there any states that do not "belong" in their local neighbourhood, elevation-wise?
- Multivariate Elements: geographical location (position) and elevation (purple-blue colour gradient as the marker for mean elevation in the chart on the left; height and colour gradient in the chart on the right).
- Comments:
  - Is the 'mean' the right measurement to use for this map?<sup>12</sup>
  - Are there ways to include other variables in this chart? 13.
  - What is going on with the scale in the legend?<sup>14</sup>
- 12: It depends on the author's purpose.

10: Western states have higher mean elevation, probably due to the presence of the

Rockies; Eastern coastal states are more

likely to suffer from rising water levels, for

11: West Virginia and Oklahoma seem to

have the "wrong" shade - is that an arte-

fact of the colour gradient and scale?

- 13: Population density with texture, for instance
- 14: No idea,,,

instance.

- **Example: Network Diagram** Lexical Distances (Figure 18.6).
  - Data:
    - speakers and language groups for 43 European languages
    - lexical distances between languages

### Some Questions and Comparisons:

- Are there languages that are lexically closer to languages in other lexical groups than to languages in their own groups?<sup>15</sup>
- Which language has the most links to other languages?<sup>16</sup>
- Are there languages that are lexically close to multiple languages in other groups?<sup>17</sup>.
- Is there a correlation between the number of speakers and the number of languages in a language group? <sup>18</sup>
- Does the bubble size refer only to European speakers? <sup>19</sup>

### Multivariate Elements:

- colour and cluster for language group
- line style for lexical distance
- bubble size for number of speakers

- 15: French is lexically closer to English than it is to Romanian, say.
- 16: English has 10 links.
- 17: Greek is lexically close to 5 groups
- 18: Language groups with more speakers tend to have more languages.
- 19: Portuguese seems to have as many speakers as French? Worldwide, that may be the case, but in Europe that is definitely not so.

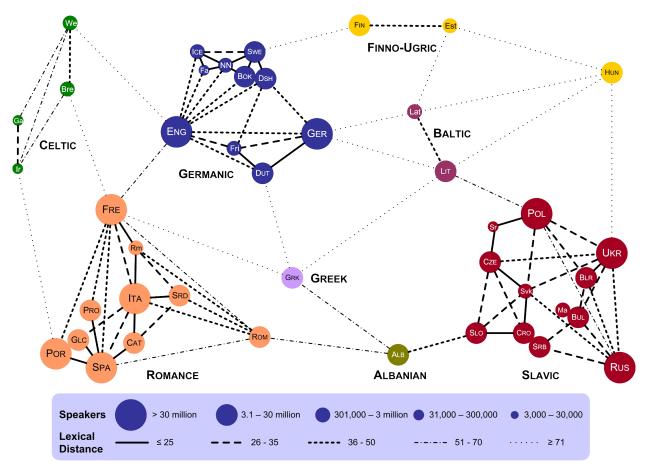

Figure 18.6: Lexical distances of European languages [6].

### Comments:

- How is lexical distance computed? Is it actually a "distance" in the mathematical sense?
- Some language pairs are not joined by links does this mean that their lexical distance is too large to be rendered?
- Are the actual geometrical distances meaningful? For instance,
   Estonian is closer to French in the chart than it is to Portuguese
   ... is it also lexically closer?<sup>20</sup>

20: Full disclosure, we are not sure if "lex-cally" is a word... but you know what we mean.

### **Example: Parallel Coordinates** Data Strings (Figure 18.7).

### ■ Data:

- demographic information for a conference's participants
- preference for using a spoon (red string) or a fork (white string) for breakfast

### Some Questions and Comparisons:

- Where is the conference most likely to be taking place?<sup>21</sup>
- Were there more men or women at the conference?<sup>22</sup>
- Can we see a correlation between age and height, or height and weight?<sup>23</sup>
- 21: Most strings go through Europe (conference taking place in Barcelona, in fact).
- 22: Seems about 50-50, but note the one string bypassing the gender axis completely evidence of sub-optimal questionnaire design?
- 23: There is likely to be one, but the inclusion of "status" and "left/right handedness" between the pairs of interest makes it impossible to tell.

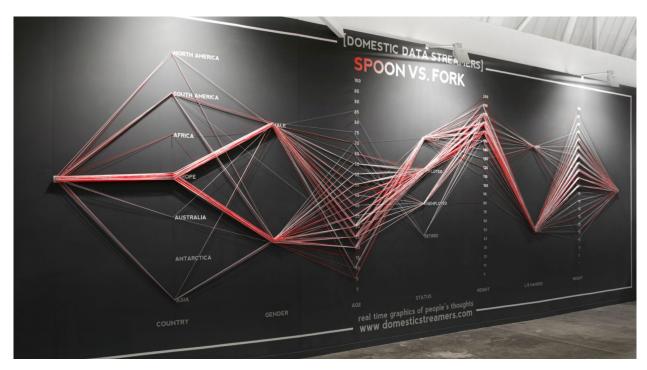

Figure 18.7: Physical visualization of people's demographics [Domestic Data Streamers ♂].

### Multivariate Elements:

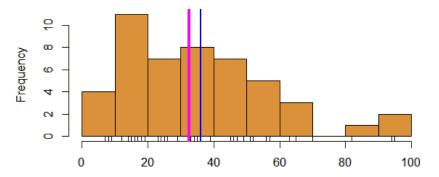

- seven demographic measurements (country (?), gender, age, status, height, left/right handed, weight)
- colour to represent the preference (spoon vs. fork)

### Comments:

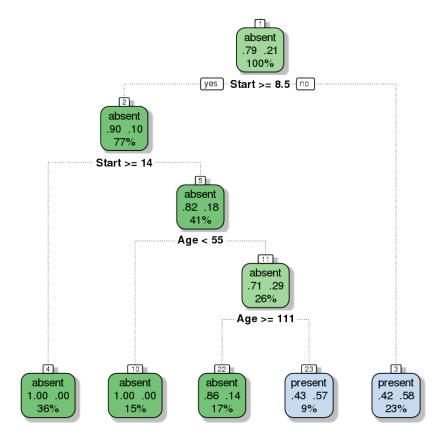

- There does not seem to a link between the colour of the string and the measurements – it seems as though the spoon vs. fork question is a red herring (or at least a way to get attendees to participate in the hands-on data collection exercise)
- Are the selected scales reasonable? Why include heights below 60cms?

### 18.1.4 Visualization Catalogue

Here are some examples of other types of visualizations; more comprehensive catalogues can be found in [1, 2, 3, 21, 13], among others.

**Figure 18.8:** Histogram: reported weekly work hours (personal file).

**Figure 18.9:** Decision Tree: classification scheme for the kyphosis dataset (personal file).

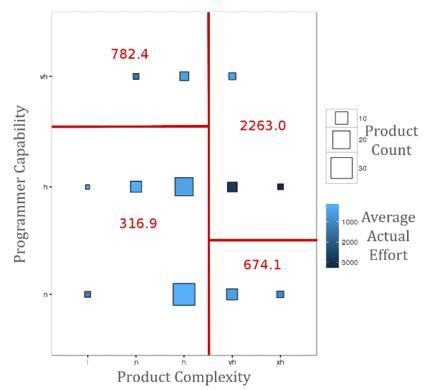

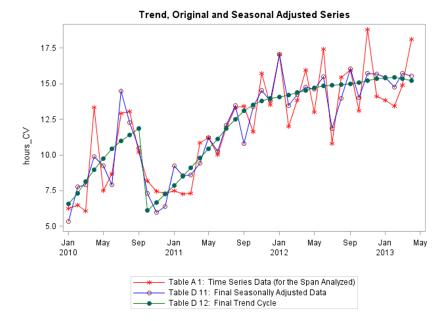

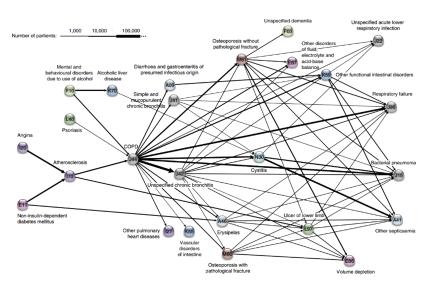

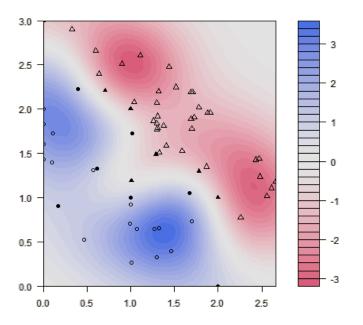

Figure 18.10: Decision tree bubble chart: estimated average project effort (in red) overlaid over product complexity, programmer capability, and product count in NASA's COCOMO dataset (personal file).

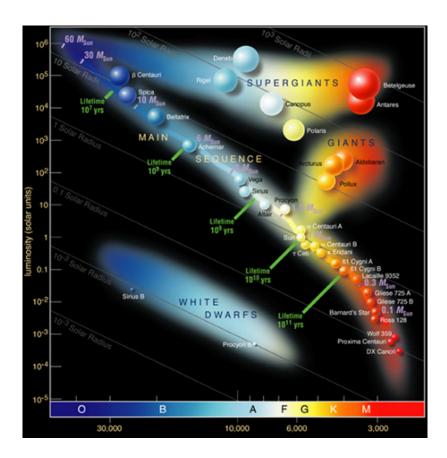

**Figure 18.11:** Time series: trend, seasonality, shifts of a supply chain metric (personal file).

**Figure 18.12:** Association rules network: diagnosis network around COPD in the Danish Medical Dataset [@Jensen].

**Figure 18.13:** Classification scatterplot: artificial dataset (personal file).

**Figure 18.14:** Classification bubble chart: Hertzsprung-Russell diagram of stellar evolution (European Southern Observatory).

### **18.1.5** A Word About Accessibility

While visual displays can help provide analysts with insight, some work remains to be done in regard to visual impairment – short of describing the features/emerging structures in a visualization, graphs can at best succeed in conveying relevant information to a subset of the population.

The onus remains on the analyst to not only produce **clear** and **meaningful** visualizations (through a clever use of **contrast**, say), but also to describe them and their features in a fashion that allows all to "see" the insights. One drawback is that in order for this description to be done properly, the analyst needs to have seen all the insights, which is not always possible. Examples of "data physicalizations" can be found in [5].<sup>24</sup>

## 24: There is a lot more to say on the topic (see [1], for instance).

### 18.2 Principles of Analytical Design

In his 2006 offering *Beautiful Evidence*, E. Tufte highlights what he calls the **Fundamental Principles of Analytical Design** [18]. Tufte suggests that we present evidence to assist our thinking processes [18, p.137].

In this regard, his principles seem universal – a strong argument can be made that they are dependent neither on technology nor on culture.

Reasoning (and communicating our thoughts) is intertwined with our lives in a causal and dynamic multivariate Universe (the 4 dimensions of space-time making up only a small subset of available variates); whatever cognitive skills allow us to live and evolve can also be brought to bear on

the presentation of evidence. Tufte also highlights a particular symmetry to visual displays of evidence, being that **consumers of charts should be seeking exactly what producers of charts should be providing** (more on exactly what that is in a little bit).

Physical science displays tend to be less descriptive and verbal, and more visual and quantitative; up to now, these trends have tended to be reversed when dealing with evidence displays about human behaviour.

In spite of this, Tufte argues that his principles of analytical design can also be applied to social science and medicine. To demonstrate the universality of his principles, he describes in detail how they are applied to Minard 's celebrated *March to Moscow*. <sup>25</sup>

Rather, we will illustrate the principles with the help of the Gapminder's Foundation 2012 Health and Wealth of Nations data visualization (see Figure 18.4), a bubble chart plotting 2012 life expectancy, adjusted income per person in USD (log-scaled), population, and continental membership for 193 UN members and 5 other countries (a high-resolution version of the image is available on the Gapminder website  $\square$ .)

Tufte identifies 6 basic properties of superior analytical charts:

- their ability to conduct meaningful comparisons;
- their ability to identify underlying structures and potential causal avenues;
- their incorporation of multivariate links;
- their ease of **integration** and use of **relevant data**;
- their honest and complete documentation, and
- their primary focus on content

### 18.2.1 Comparisons

"Show comparisons, contrasts, differences." [18, p.127]

**Comparisons** come in varied flavours: for instance, one could compare a:

- unit at a given time against the same unit at a later time;
- unit's component against another of its components;
- unit against another unit,
- or any number of combinations of these flavours.

Tufte further explains that

[...] the fundamental analytical act in statistical reasoning is to answer the question "Compared with what?" Whether we are evaluating changes over space or time, searching big data bases, adjusting and controlling for variables, designing experiments, specifying multiple regressions, or doing just about any kind of evidence-based reasoning, the essential point is to make intelligent and appropriate comparisons [emphasis added]. Thus, visual displays [...] should show comparisons. [18, p.127]

25: His lengthy analysis of the image is well worth the read [18, pp.122-139] – it will not be repeated here (although other aspects of the chart are discussed in [1]).

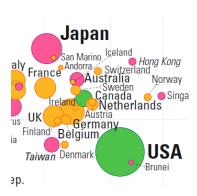

Not every comparison will be insightful, but avoiding comparisons altogether is equivalent to producing a useless display, built from a single datum.

**Health and Wealth of Nations** First, note that each bubble represents a different country, and that the location of each bubble's centre is a precise point corresponding to the country's life expectancy and its GDP per capita. The size of the bubble correlates with the country's population and its colour is linked to continental membership.

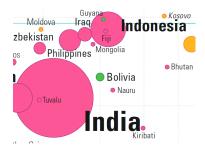

The chart's compass<sup>26</sup> provides a handy comparison tool:

- a bubble further to the right (resp. the left) represents a "wealthier" (resp. "poorer") country;
- a bubble further above (resp. below) represents a "healthier" (resp. "sicker") country.

A comparison between Japan, Germany and the USA shows that Japan is healthier than Germany, which is itself healthier than the USA (as determined by life expectancy) while the USA is wealthier than Germany, which is itself wealthier than Japan (as determined by GDP per capita, see Figure 18.15).<sup>27</sup>

It is possible for two countries to have roughly the same health and the same wealth: consider Indonesia and Fiji, or India and Tuvalu, for instance (see Figure 18.16).

In each pair, the centres of both bubbles (nearly) overlap: any difference in the data must be found in the bubbles' area or in their colour.

Countries can also be compared against **world values** for life expectancy and GDP per capita (a shade under 70 years and in the neighbourhood of \$11*K*, respectively). The world's mean life expectancy and income per person are traced in light blue (see Figure 18.17).<sup>28</sup>

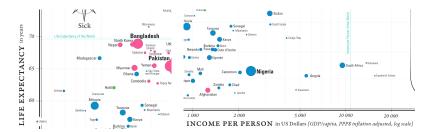

27: Health and wealth are such complicated concepts that they cannot simply be represented by a single measure (and perhaps not even by multiple measures). Nevertheless, we use them as proxies in this example.

**Figure 18.15:** Comparisons in the Gapminder chart: country-to-country.

**Figure 18.16:** Comparisons in the Gapminder chart: country-to-country overlap.

28: We see for instance, that Nepal's life expectancy is a just a hair below the life expectancy on the planet, and that Botswana's GDP per capita is above the global income per person.

**Figure 18.17:** Comparisons in the Gapminder chart: country-to-world-life-expectancy (left) and country-to-world-income-per-person (right).

Wealthier, healthier, poorer, and sicker are relative terms, but we can also use them to classify the world's nations with respect to these mean values, "wealthier" meaning "wealthier than the average country", and so on.

### 18.2.2 Mechanism, Structure, Explanation

"Show causality, mechanism, explanation, systematic structure." [18, p.128]

In essence, this is the core principle behind data visualization: the display needs to explain *something*, it needs to provide (potential) links between cause and effect. As Tufte points out,

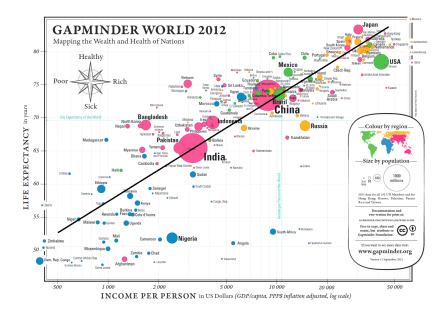

[...] often the reason that we examine evidence is to understand causality, mechanism, dynamics, process, or systematic structure [emphasis added] [...] Reasoning about reforms and making decisions also demands causal logic. To produce the desired effects, we need to know and govern the causes; thus "policy-thinking is and must be causality-thinking". [18, p.128], [4]

#### Note also that

simply collecting data may provoke thoughts about cause and effect: measurements are inherently comparative, and comparisons promptly lead to reasoning about various sources of differences and variability. [18, p.128]

Finally, if the visualization can be removed without diminishing the narrative, then that chart should in all probability be excluded from the final product, no matter how pretty and modern it looks, or how costly it was to produce.

**Health and Wealth of Nations** At a glance, the relation between life expectancy and the logarithm of income per person seems to be increasing more or less linearly. Without access to the data, the exact parameter values cannot be estimated analytically, but an approximate line-of-best-fit has been added to the chart in Figure 18.18.

**Figure 18.18:** Approximate line of best fit for the Gapminder chart.

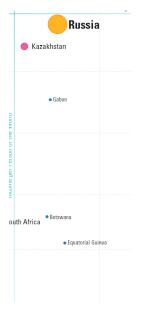

Using the points (10K, 73.5) and (50K, 84.5) yields a line with equation

Life Expectancy  $\approx 6.83 \times \ln(\text{Income Per Person}) + 57.76$ .

The exact form of the relationship and the numerical values of the parameters are of little significance at this stage – the key insight is that wealthier countries appear to be healthier, generally, and *vice-versa*.<sup>29</sup>

The chart also highlights an interesting feature in the data, namely that the four quadrants created by separating the data along the Earth's average life expectancy and GDP per capita do not all host similar patterns.

Naïvely, it might have been expected that each of the quadrants would contain about 25% of the world's countries (although the large population of China and India muddle the picture somewhat). However, one quadrant is substantially under-represented in the visualization. Should it come as a surprise that there are so few "wealthier" yet "sicker" countries? (see Figure 18.19).

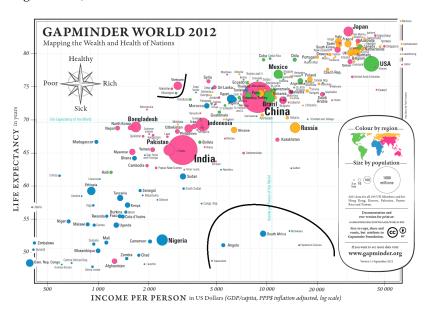

29: Whether wealth drives health, health drives wealth, or some other factor(s) [education?] drive both wealth and health cannot be answered without further analysis and access to knowledge external to the chart.

Figure 18.19: Close-up, bottom right quadrant.

It could even be argued that Russia and Kazakhstan are in fact too near the "separators" to really be considered clear-cut members of the quadrant, so that the overwhelming majority of the planet's countries are found in one of only three quadrants.

In the same vein, when we consider the data visualization as a whole, there seems to be one group of outliers below the main trend, to the right, and to a lesser extent, one group above the main trend, to the left (see Figure 18.20).

**Figure 18.20:** Potential outliers in the Gapminder chart.

30: Could income disparity between a poorer majority and a wealthier minority push the bubble to the right, while lower life expectancy of the majority drives the overall life expectancy downward?

31: We discuss the topic further in the exercises.

These cry out for an explanation: South Africa, for instance, has a relatively high GDP per capita but a low life expectancy.<sup>30</sup> This brings up a crucial point about data visualization: it seems virtually certain that the racial politics of *apartheid* played a major role in the position of the South African outlier, but the chart emphatically **DOES NOT** provide a proof of that assertion.<sup>31</sup>

Charts suggest, but "proofs" come from deeper **domain-specific analy-ses**.

### 18.2.3 Multivariate Analysis

"Show multivariate data; that is, show more than 1 or 2 variables." [18, p.130]

In an age where data collection is becoming easier by the minute, this seems like a no-brainer: why waste time on uninformative univariate plots? Indeed,

nearly all the interesting worlds (physical, biological, imaginary, human) we seek to understand are inevitably multivariate in nature. [18, p.129]

Furthermore, as Tufte suggest,

the analysis of cause and effect, initially bivariate, quickly becomes multivariate through such necessary elaborations as the conditions under which the causal relation holds, interaction effects, multiple causes, multiple effects, causal sequences, sources of bias, spurious correlation, sources of measurement error, competing variables, and whether the alleged cause is merely a proxy or a marker variable (see for instance, [11]). [18, p.129]

While we should not dismiss low-dimensional evidence simply because it is low-dimensional, Tufte cautions that

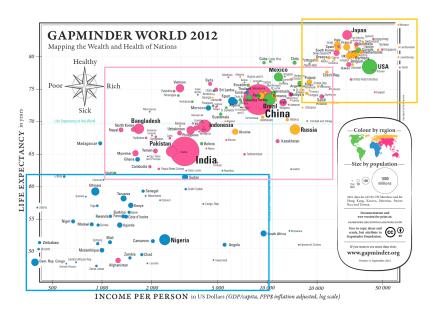

reasoning about evidence should not be stuck in 2 dimensions, for the world we seek to understand is profoundly multivariate [emphasis added]. [18, p.130]

Analysts may question the ultimate validity of this principle: after all, doesn't Occam's Razor warn us that "it is futile to do with more things that which can be done with fewer"? This would seem to be a fairly strong admonition to not reject low-dimensional visualizations out of hand. This interpretation depends, of course, on what it means to "do with fewer": are we attempting to "do with fewer", or to "do with fewer"?

If it is the former, then we can produce simple charts to represent the data (which quickly balloons into a multivariate meta-display), but any significant link between 3 and more variables is unlikely to be shown, which drastically reduces the explanatory power of the charts.

If it is the latter, the difficulty evaporates: we simply retain as many features as are necessary to maintain the desired explanatory power.

**Health and Wealth of Nations** Only 4 variables are represented in the display, which we could argue just barely qualifies the data as multivariate. The population size seems uncorrelated with both of the axes' variates, unlike continental membership: there is a clear divide between the West, most of Asia, and Africa (see Figure 18.21.

**Figure 18.21:** Potential outliers in the Gapminder chart.

This "clustering" of the world's nations certainly fits with common wisdom about the state of the planet, which provides some level of validation for the display, but it not (by far) the **only way** to cluster the observations.

Another multivariate interpretation is afforded by Figure 18.18: countries in the upper right corner (whose location is given by 2 variables) are coloured differently (according to a third variable) than those in the lower left corner.

Other variables could also be considered or added, notably the year, allowing for bubble movement: one would expect that life expectancy and GDP per capita have both been increasing over time. The Gapminder Foundation's online tool [2] can build charts with other variates, leading to interesting inferences and suggestions.

### 18.2.4 Integration of Evidence

"Completely integrate words, numbers, images, diagrams." [18, p.131]

Data does not live in a vacuum. Tufte's approach is clear:

the evidence doesn't care what it is – whether word, number, image. In reasoning about substantive problems, what matters entirely is the evidence, not particular modes of evidence [emphasis added]. [18, p.130]

The main argument is that evidence from data is better understood when it is presented with context and accompanying meta-data. Indeed,

words, numbers, pictures, diagrams, graphics, charts, tables belong together [emphasis added]. Excellent maps, which are the heart and soul of good practices in analytical graphics, routinely integrate words, numbers, line-art, grids, measurement scales. [18, p.131]

Finally, Tufte makes the point that we should think of data visualizations and data tables as elements that provide vital evidence, and as such they should be integrated in the body of the text:

tables of data might be thought of as paragraphs of numbers, tightly integrated with the text for convenience of reading rather than segregated at the back of a report. [...] Perhaps the number of data points may stand alone for a while, so we can get a clean look at the data, although techniques of layering and separation may simultaneously allow a clean look as well as bringing other information into the scene. [18, p.131]<sup>32</sup>

When authors and researchers select a single specific method or mode of information during the inquiries, the focus switches from "can we explain what is happening?" to "can the method we selected explain what is happening?"

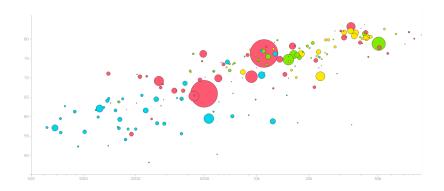

There is an art to **method selection**, and experience can often suggest relevant methods, but remember that "when all one has is a hammer,

32: There is a flip side to this, of course, and it is that charts and displays should be annotated with as much text as is required to make their **context clear**.

everything looks like a nail": the goal should be to use the necessary evidence to shed light on "what is happening". If that goal is met, what modes of evidence were used is irrelevant.

**Health and Wealth of Nations** The various details attached to the chart (such as country names, font sizes, axes scale, grid, and world landmarks) provide substantial benefits when it comes to consuming the display. ay become lost in the background, with the consequence of being taken for granted, but their presence is still crucial.

Case in point, compare the display obtained from the same data, but without integration of evidence in Figure 18.22 – who could reasonably guess what it is about without context?

**Figure 18.22:** Non-integrated Gapminder

### 18.2.5 Documentation

"Thoroughly describe the evidence. Provide a detailed title, indicate the authors and sponsors, document the data sources, show complete measurement scales, point out relevant issues." [18, p.133]

We cannot always tell at a glance whether a pretty graphic speaks the truth or presents a relevant piece of information. Documented charts may provide a hint, as

the credibility of an evidence presentation depends significantly on the quality and integrity of the authors and their data sources. Documentation is an essential mechanism of quality control for displays of evidence. Thus authors must be named, sponsors revealed, their interests and agenda unveiled, sources described, scales labeled, details enumerated [emphasis added]. [18, p.132]

Depending on the context, questions and items to address could include:

- What is the title/subject of the visualization?
- Who did the analysis? Who created the visualization? (if distinct from the analyst(s))
- When was the visualization published? Which version of the visualization is rendered here?

- Where did the underlying data come from? Who sponsored the display?
- What assumptions were made during data processing and cleanup?
- What colour schemes, legends, scales are in use in the chart?

It is not obvious whether all this information can fit inside a single chart in some cases. But, keeping in mind the principle of integration of evidence, charts should not be presented in isolation in the first place, and some of the relevant information can be provided in the text, on a webpage, or in an accompanying document.

This is especially important when it comes to discussing the methodological assumptions used for data collection, processing, and analysis. An honest assessment may require sizable amounts of text, and it may not be reasonable to include that information with the display:<sup>33</sup>

publicly attributed authorship indicates to readers that someone is taking responsibility for the analysis; conversely, the absence of names signals an evasion of responsibility. [...] **People do things, not agencies, bureaus, departments, divisions** [emphasis added]. [18, pp.132-133]

**Health and Wealth of Nations** The Gapminder map might just be one of the best-documented charts in the data visualization ecosystem. Let us see if we can answer the questions suggested above.

- What is the title/subject of the visualization? The health and wealth of nations in 2012, using the latest available data (2011).
- Who did the analysis? Who sponsored the display? Who created the visualization? The analysis was conducted by the Gapminder Foundation; the map layout was created by Paulo Fausone. No data regarding the sponsors is found on the chart or in the documentation. It seems plausible that there were none.
- When was the visualization published? Which version is rendered here? The 11th version of the chart was published in September 2012.
- Where did the underlying data come from? What assumptions were made during data processing and clean-up? Typically, the work that goes into preparing the data is swept under the carpet in favour of the visualization itself; there are no explicit source of data on this chart, for instance. However, there is a URL in the legend box that leads to detailed information ☑ . For most countries, life expectancy data was collected from:
  - the Human Mortality database;
  - the UN Population Division World Population Prospects;
  - files from historian James C. Riley;
  - the Human Life Table database;
  - data from diverse national statistical agencies;
  - the CIA World Fact book;
  - the World Bank, and
  - the South Sudan National Bureau of Statistics.

33: In that case, a link to the accompanying documentation should be provided.

Benchmark 2005 GDP data was derived via regression analysis from International Comparison Program data for 144 countries, and extended to other jurisdictions using another regression against data from:

- the UN Statistical Division;
- Maddison Online;
- the CIA World Fact book, and
- estimates from the World Bank.

The 2012 values were then derived from the 2005 benchmarks using long-term growth rates estimate from:

- Maddison Online;
- Barro & Ursua;
- the UN Statistical Division;
- the Penn World Table (mark 6.2);
- the IMF's World Economic Outlook database;
- the World Development Indicators;
- Eurostat, and
- national statistical offices or some other specific publications.

Population estimates were collated from:

- the UN Population Division World Population Prospects;
- Maddison Online;
- Mitchell's International Historical Statistics;
- the UN Statistical Division;
- the US Census Bureau;
- national sources, and
- undocumented sources and "guesstimates".

Exact figures for countries with a population below 3 million inhabitants were not needed as this marked the lower end of the chart resolution.

• What colour schemes, legends, scales are in use in the chart? The *Legend Inset* is fairly comprehensive (see Figure 18.23).

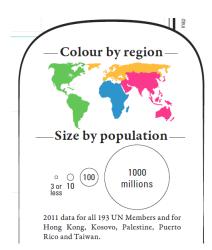

Figure 18.23: Legend inset for the Gapminder chart.

Perhaps the last item of note is that the scale of the axes differs: life expectancy is measured linearly, but GDP per capita is measured on a logarithmic scale.

### 18.2.6 Content First and Foremost

"Analytical presentations ultimately stand of fall depending on the quality, relevance, and integrity of their content." [18, p.136]

Any amount of time and money can be spent on graphic designers and focus groups, but

the most effective way to improve a presentation **is to get better content** [emphasis added] [...] design devices and gimmicks cannot salvage failed content. [...] The first questions in constructing analytical displays are not "How can this presentation use the color purple?" Not "How large must the logotype be?" Not "How can the presentation use the Interactive Virtual Cyberspace Protocol Display Technology?" Not decoration, not production technology. The first question is "What are the content-reasoning tasks that this display is supposed to help with?" [emphasis added] [18, p.136]

The main objective is to produce a compelling narrative, which may not necessarily be the one that was initially expected to emerge from a solid analysis of sound data. Simply speaking, the visual display should assist in explaining the situation at hand and in answering the original questions that were asked of the data.

**Health and Wealth of Nations** How would we answer the following questions:

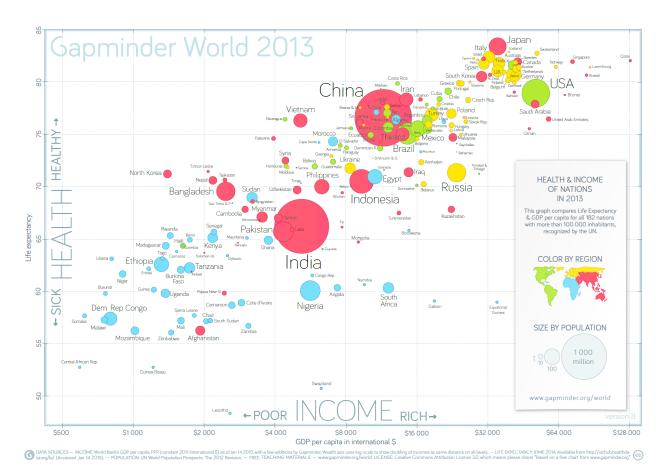

- Do we observe similar patterns every year?
- Does the shape of the relationship between life expectancy and log-GDP per capita vary continuously over time?
- Do countries ever migrate large distances in the display over short periods?
- Do exceptional events affect all countries similarly?
- What are the effects of secession or annexation?

The 2012 Health and Wealth of Nations data represent a single datum in the general space of data visualizations; in this context, getting better content means getting data for other years, as well as for 2012 (such as in Figure 18.24 and the Gapminder Tools  $\[ \]$  .)

Are the same countries still outlying observations? Is the relationship between life expectancy and GPD per capita still linear? Are the country groupings the same? Is the bottom right quadrant still empty?

Is that story **more or less** similar? Is it **significantly** different?

It should be noted that Tufte's views are not shared by every practitioner. We mentioned it in Section 18.1.2, but it bears repeating: the name of the game is **conveying insights** – any visual that helps with that is on the table. It is true that if a chart satisfies Tufte's principles, the chance that it will convey insights is good. But it is not necessarily a **requirement**.

**Figure 18.24:** Life expectancy and income per capita in 2013, by nation (Gapminder Foundation ♂).

### 18.3 Introduction to Dashboards

Dashboards are a helpful way to **communicate** and **report** data. They are versatile in that they support multiple types of reporting. Dashboards are predominantly used in business intelligence contexts, but they are being used more frequently to communicate data and visualize analysis for non-business services also. Popular dashboarding platforms include Tableau, and Power BI, although there are other options, such as Excel, R + Shiny, Geckoboard, Matillion, JavaScript, etc.

These technologies aim to make creating data reports as simple and user-friendly as possible. They are intuitive and powerful; creating a dashboard with these programs is quite easy, and there are tons of how-to guides available online [9, 10, 20].

In spite of their ease of use, however, dashboards suffer from the same limitations as other forms of data communication, to wit: how can results be **conveyed effectively** and how can an **insightful data story** be relayed to the desired audience? Putting together a "good" dashboard is more complicated than simply learning to use a dashboarding application.

### 18.3.1 Dashboard Fundamentals

Effective dashboarding requires that the designers answer questions about the planned-for display:

- who is the target audience?
- what value does the dashboard bring?
- what type of dashboard is being created?

Answering these questions can guide and inform the visualization choices that go into creating dashboards.

Selecting the **target audience** helps inform data decisions that meet the needs and abilities of the audience. When thinking of an audience, consider their **role** (what decisions do they make?), their **workflow** (will they use the dashboard on a daily basis or only once?), and **data expertise level** (what is their level of data understanding?).

When creating a dashboard, its important to understand (and keep in mind) why one is needed in the first place – does it find **value** in:

- helping managers make decisions?
- educating people?
- setting goals/expectations?
- evaluating and communicating progress?

Dashboards can be used to communicate numerous concepts, but not all of them can necessarily be displayed in the same space and at the same time so it becomes important to know where to direct the focus to meet individual dashboards goals. Dashboard decisions should also be informed by the **scope**, the **time horizon**, the required **level of detail**, and the dashboard's **point-of-view**. In general,

- the scope of the dashboard could be either broad or specific an
  example of a broad score would be displaying information about
  an entire organization, whereas a specific scope could focus on a
  specific product or process;
- the time horizon is important for data decisions it could be either historical, real-time, snapshot, or predictive:
  - historical dashboards look at past data to evaluate previous trends:
  - real-time dashboards refresh and monitor activity as it happens;
  - snapshot dashboards show data from a single time point, and
  - predictive dashboards use analytical results and trend-tracking to predict future performances;
- the **level of detail** in a dashboard can either be high level or drill-able **high level** dashboards provide only the most critical numbers and data; **drill-able** dashboards provide the ability to "drill down" into the data in order to gain more context.
- the dashboard point of view can be prescriptive or exploratory

   a prescriptive dashboard prescribes a solution to an identified problem by using the data as proof; an exploratory dashboard uses data to explore the data and find possible issues to be tackled.

The foundation of good dashboards comes down to deciding what information is most important to the audience in the context of interest; such dashboards should have a **core theme** based on either a **problem to solve** or a **data story to tell**, while removing extraneous information from the process.

### 18.3.2 Dashboard Structure

The dashboard structure is informed by four main considerations:

- form format in which the dashboard is delivered;
- layout physical look of the dashboard;
- design principles fundamental objectives to guide design,
- **functionality** capabilities of the dashboard.

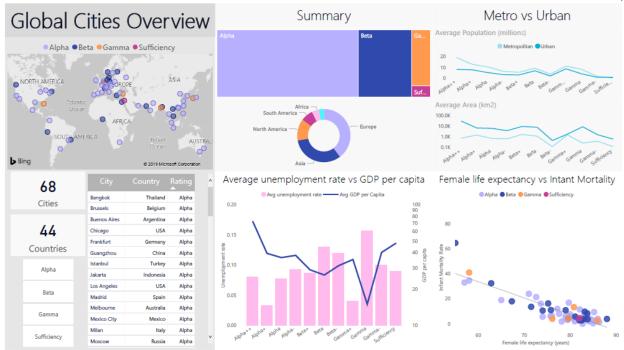

Dashboards can be presented on paper, in a slide deck, in an online application, over email (messaging), on a large screen, on a mobile phone screen, etc.

Selecting a **format** that suits the dashboard needs is a necessity; various formats might need to be tried before arriving at a final format decision.

The structure of the dashboard itself is important because visuals that tell similar stories (or different aspects of the same story) should be kept close together, as **physical proximity of interacting components** is expected from the viewers and consumers. Poor structural choices can lead to important dashboard elements being undervalued.

The dashboard shown in Figure 18.25 provides an example of **group visuals** that tell similar stories.<sup>34</sup>

34: The corresponding Power BI file can be found on the Data Action Lab ♂ website).

**Figure 18.25:** An exploratory dashboard showing metrics about various cities ranked on the Global Cities Index. The dashboard goal is to allow a general audience to **compare and contrast** the various globally ranked cities – statistics that contribute to a 'higher' ranking immediately pop out. Viewers can also very easily make comparisons between high- and low-ranking cities. The background is kept neutral with a fair amount of blank space in order to keep the dashboard open and easy to read. The colours complement each other (*via* the use of a colour theme picker in Power BI) and are clearly indicative of ratings rather than comparative statistics (personal file).

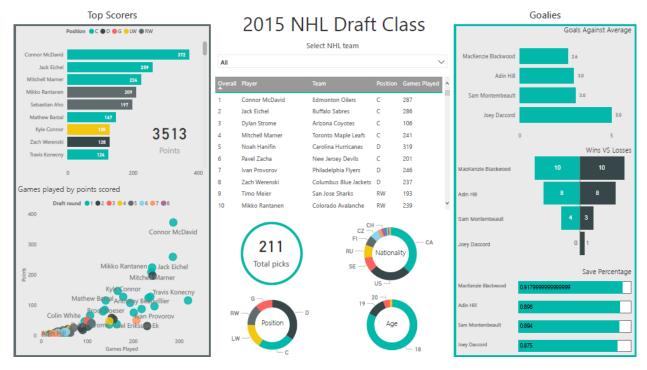

Knowing which visual displays to use with the "right" data helps dashboards achieve structural integrity:

- distributions can be displayed with bar charts and scatter plots;
- compositions with pie charts, bar charts, and tree maps;

- **comparisons** use **bubble charts** and **bullet plots**, and
- trends are presented with line charts and area plots.

An interesting feature of dashboard structure is that it can be used to guide **viewer attention**; critical dashboard elements can be highlighted with the help of visual cues such as use of **icons**, **colours**, and **fonts**. Using **filters** is a good way to allow dashboard viewers of a dashboard to customize the dashboard scope (to some extent) and to investigate specific data categories more closely.

The dashboard shown in Figure 18.26 provides an example of a dashboard that makes use of an interactive filter to analyze data from specific categories.

**Figure 18.26:** An exploratory dashboard showing information about the National Hockey League draft class of 2015. The dashboard displays professional statistics (as of August 2019) of hockey players drafted into the NHL in 2015, as well as their overall draft position. This dashboard allows **casual hockey fans** to **evaluate the performance** of players drafted in 2015. It provides demographic information to give context to possible market deficiencies during this draft year (i.e., defence players were drafted more frequently than any other position). This dashboard is designed to be interactive; the filter tool at the top allows dashboard viewers to drill-down on specific teams (personal file).

### 18.3.3 Dashboard Design

An understanding of design improves dashboards; **dissonant** designs typically make for poor data communication. Design principles are discussed in [19, 18, 16, 2, 14]. For dashboards, the crucial principles relate to the use of **grids**, **white space**, **colour**, and **visuals**. When laying out a dashboard, **gridding** helps direct viewer attention and makes the space easier to parse.<sup>35</sup>

In order to help viewers avoid becoming overwhelmed by clutter or information overload, consider leaving enough **blank space** around and within the various charts.<sup>36</sup> In general, clutter shuts down the communication process – Figure 18.27 provides two impressive breakdown examples.

- 35: The various visuals are **aligned** in a grid format to lay the data out in a clean, readable manner in Figure 18.25.
- 36: While the dashboard of Figure 18.26 displays a lot of information, there is a lot of blank/white space between the various visuals, which provides viewers with space to breathe.

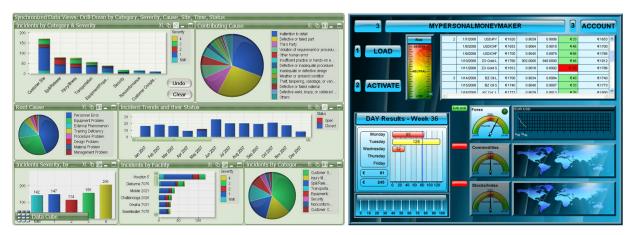

Figure 18.27: Anonymous 'ugly' dashboards [12, 8]; how about these data communication breakdowns?

**Colour** provides meaning to data visualizations – bright colours, for instance, should be used as alarms as they draw the viewer's attention. Colour themes create cohesiveness, improving the overall readability of a dashboard.<sup>37</sup>

That being said, dashboards that are **elegant** (as well as **truthful** and **functional**) will deliver a bigger bang for their buck [2, 3]. In the same vein, keep in mind that all dashboards are by necessity **incomplete**.<sup>38</sup>

Finally, designers and viewers alike must remember that a dashboard can **only be as good as the data it uses**; a dashboard with badly processed or unrepresentative data, or which is showing the results of poor analyses, cannot be an effective communication tool, independently of design.

### **18.3.4 Examples**

Dashboards are used in varied contexts, such as:

- interactive displays that allows people to explore motor insurance claims by city, province, driver age, etc.;
- a PDF file showing key audit metrics that gets e-mailed to a Department's DG on a weekly basis;
- a wall-mounted screen that shows call centre statistics in real-time;
- a mobile app that allows hospital administrators to review wait times on an hourly- and daily-basis for the current year and the previous year; etc.

**The Ugly** While the previous dashboards all have some strong elements, it is a harder to be generous for the two examples provided in Figure 18.27.<sup>39</sup> The first of these is simply "un-glanceable" and the overuse of colour makes it unpleasant to look at; the second one features 3D visualizations (rarely a good idea), distracting borders and background, lack of filtered data, insufficient labels and context, among others.

- 37: There are no perfect dashboards no collection of charts will ever suit everyone who encounters it.
- 38: A good dashboard may still lead to dead ends, but it should allow its users to ask: "Why? What is the root cause of the problem?"

<sup>39:</sup> Is it easy to figure out, at a glance, who their audience is meant to be? What are their strengths (do they have any)? What are their limitations? How could they be improved? What can they be used for?

**The Good** Good dashboards, on the other hand, simply breathe. The number of charts on each page is small, boxes are eschewed, simple colour schemes are preferred, and the canvas is quiet (see Figures 18.28 and 18.29, for instance). We discuss topics relating to data storytelling and design principles in [1].

**Golden Rules** In a (deleted) blog article, N. Smith posted his Golden Rules:

- consider the audience (who are you trying to inform?does the DG really need to know that the servers are operating at 88% capacity?);
- select the right type of dashboard (operational, strategic/executive, analytical);
- group data logically, use space wisely (split functional areas: product, sales/marketing, finance, people, etc.);
- make the data relevant to the audience (scope and reach of data, different dashboards for different departments, etc.);
- avoid cluttering the dashboard (present the most important metrics only), and
- refresh your data at the right frequency (real-time, daily, weekly, monthly, etc.).

With dashboards, as with data analysis and data visualization in general, there is no substitute for **practice**: the best way to become a proficient builder of dashboards is to ... well, to go out and build dashboards, try things out, and, frequently, to stumble and learn from the mistakes.

### 18.4 Exercises

You may wish to consult [1] (in particular, Chapters 11-13) for instructions on how to use R, ggplot2, and/or Power BI for this chapter's exercises.

- 1. Find examples of data presentations that you consider to be particularly insightful and/or powerful. Discuss their strengths and weaknesses.
- 2. Find examples of data presentations that you consider to be particularly misleading and/or useless. Discuss their strengths and
- 3. How do you think new technologies (e.g. virtual or augmented reality, 3D-printing, wearable computing) will influence data presentations?
- 4. Consider the following datasets:
  - GlobalCitiesPBI.csv 🗗
  - 2016collisionsfinal.csv 🗗
  - polls\_us\_election\_2016.csv 🖒, and
  - HR\_2016\_Census\_simple.xlsx 🗗.
  - a) Create a data dictionary for this dataset. Establish a list of variables that you think are crucial to a good understanding of the dataset. Justify your choices.
  - b) Create (at least) 5 bivariate/univariate visualizations that can help you understand the dataset.

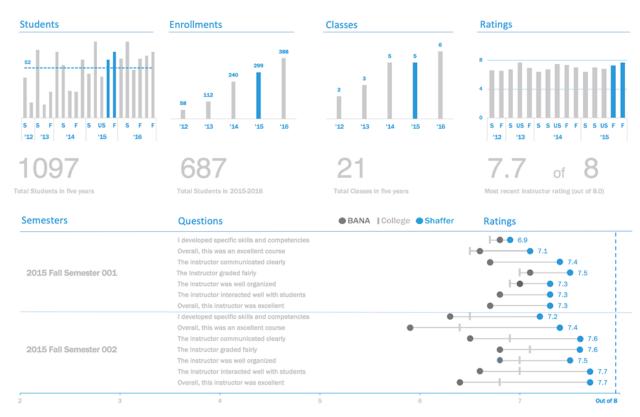

- c) Produce (at least) 3 "definitive" visualizations for the dataset. Use the principles discussed in class (including documentation, legends, annotations, Multiple I's, etc.). Emphasis should be placed on content AND on presentation (suggestions: consider creating a reasonably high number of charts using a random selection of a random number of variables in order to minimize the odds of missing out on useful information).
- 5. Repeat the previous question with any dataset of your liking.
- 6. Identify a scenario for which a dashboard could prove useful. Determine specific questions that the dashboard could help answer or insights that it could provide. Identify data sources and data elements that could be fed into your dashboard. Design a display (with pen and paper) with mock charts. What are the strengths and limitations of your dashboard? Is it functional? Elegant?
- 7. The remaining exercises use the Gapminder Tools (there is also an offline version).
  - a) At what point in the data science workflow do you think that visualizations of this nature could be useful?
  - b) What are the ways in which observations could be anomalous? Have you found any such anomalies? Do you have explanations for them? In particular, consider the case of South Africa in 2012, which appears to be a clear outlier. Follow the path of the South African bubble from 1975 to 2020, in relation to the general pattern. Does the apartheid/income inequity explanation suggested in the text still make sense?
  - c) Pick 2+ "definitive" visualizations (methods, variables, etc.) other than the default configuration. What are some important insights?
  - d) How would you describe the insights of step 3 without resorting to visual vocabulary?
  - e) Can you think of ways in which the data of interest to you in your day-to-day activities could benefit from the same treatment? What situations could you explore in such a scenario? How would that help your team better understand the system under consideration?
- 8. Consider the following Australian population figures, by state (in 1000s):
  - a) Graph the New South Wales (NSW) population with all defaults using plot(). Redo the graph by adding a title, a line to connect the points, and some colour.
  - b) Compare the population of New South Wales (NSW) and the Australian Capital Territory (ACT) by using the functions plot() and lines(), then add a legend to appropriately display your graph.
  - c) Use a bar chart to graph the population of Queensland (QLD), add an appropriate title to your graph, and display the years from 1917 to 2017 on the appropriate bars.
  - d) Create a light blue histogram for the population of South Australia (SA) over the years. Does this chart make sense?

Year	NSW	Vic.	Qld	SA	WA	Tas.	NT	ACT	Aust.
1917	1904	1409	683	440	306	193	5	3	4941
1927	2402	1727	873	565	392	211	4	8	6182
1937	2693	1853	993	589	457	233	6	11	6836
1947	2985	2055	1106	646	502	257	11	17	7579
1957	3625	2656	1413	873	688	326	21	38	9640
1967	4295	3274	1700	1110	879	375	62	103	11799
1977	5002	3837	2130	1286	1204	415	104	214	14192
1987	5617	4210	2675	1393	1496	449	158	265	16264
1997	6274	4605	3401	1480	1798	474	187	310	18532
2007	6889	5205	4182	1585	2106	493	215	340	21017
2017	7861	6324	4928	1723	2580	521	246	410	24599
